## STANDARD OXYGEN SENSORS

- Standard O2 sensors include dual internal seals to insure the reference sides stay sealed... extending the life of the sensor.
- The hex nut is backed away from manifold to allow easier access during removal and installation.
- The breathable Teflon membrane ensures proper clean air flow. This is important because reference air is compared to the exhaust gases across the sensor element, which generates the sensor signal. Many competitors rely solely on diffusion through the wires for reference air exchange which can be unreliable. Clean reference air improves sensor performance.
- Some competitors use a two-piece body with multiple laser welds or crimps to hold the body together. Standard uses a one-piece body with a single laser weld resulting in the best possible seal.
